---

BIO5312 FALL2017

STEPHANIE J. SPIELMAN, PHD

# Random variable

---

Random processes produce numerical outcomes:

- Number of tails in 50 coin flips
- The sum of everyone's heights

**Definition:** a random variable is a function that maps outcomes of a random process to a numeric value

- $X$  is a function (rule) that assign a number  $X(s)$  to each outcome  $s \in S$  (where  $s$  is an event in sample space  $S$ )
- r.v.'s are technically neither random nor variables...
- But, you can think of them roughly numerical outcomes of random processes

# Discrete vs continuous RV

---

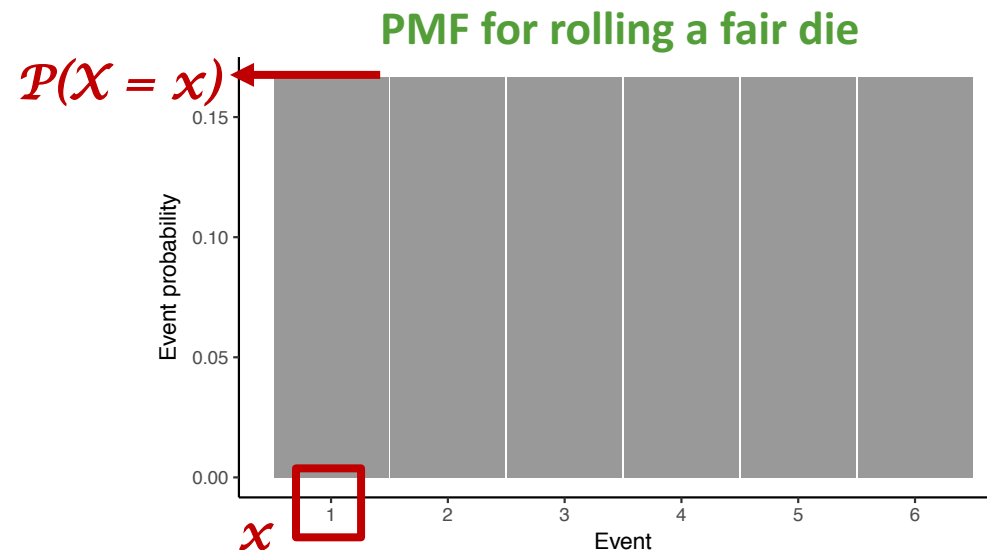

**Discrete** random variables can take on (map to) a finite number of values

**Continuous** random variables can take on (map to) innumerable/infinite values

# Expressing discrete random variables

## Probability mass function (PMF)

- Describes the values taken by a discrete r.v.  $\mathcal{X}$  and its associated probabilities
- Function that assigns, to any possible value  $x$  of a discrete r.v.  $\mathcal{X}$ , the probability  $\mathcal{P}(\mathcal{X} = x)$

# PMF properties

---

$$0 \leq P(X = x) \leq 1$$

$$\sum P(X = x) = 1$$

PMF is simply a fancier term for a discrete probability distribution

# Expressing discrete random variables

## Cumulative distribution function (CDF)

- Function defined, for a specific value  $x$  of a discrete r.v.  $\mathcal{X}$ , as  $\mathcal{F}(x) = \mathcal{P}(\mathcal{X} \leq x)$

# CDF properties

---

$$0 \leq F(X) \leq 1$$

CDF functions are non-decreasing

# PMF vs CDF

---

PMF: What is the probability of event  $X$ ?

CDF: What is the sum of probabilities for all events  $\leq X$ ?

# Expectation and spread of random variables

---

The **expectation** of a r.v. is the probability-weighted average of all possible values (i.e., mean)

- $\mathbb{E}(X) = \mu = \sum_i x_i p(x_i)$

The **variance** of a r.v. is defined

- $Var(X) = \sigma^2 = \mathbb{E}[(X - \mu)^2] = \sum_i [x_i^2 p(x_i)] - \mu^2$
- $Var(X) = \mathbb{E}[X^2] - \mathbb{E}[X]^2$

# Example: The Binomial distribution

---

The **binomial distribution** describes the probability of obtaining  $k$  successes in  $n$  Bernoulli trials, where the probability of success for each trial is constant at  $p$

A **Bernoulli trial** has a binary outcome (success/fail, true/false, yes/no), and  $P(\text{success}) = p$  is the same for all realizations of the trial

# The **BInS** conditions

---

To be binomially distributed, must satisfy the following:

**B**inary outcomes

**I**ndependent trials (outcomes do not influence each other)

**n** is fixed before the trials begin

**S**ame probability of success,  $p$ , for all trials

# Is it binomial?

---

A bag contains 10 balls, 7 red and 3 green.

**Situation 1:** You draw 5 balls from the bag, noting the ball color each time and then returning it to the bag. **Yes!**

**Situation 2:** You draw 5 balls from the bag, retaining each drawn ball for safe-keeping so you can play catch at any moment. **No** 😞

**Situation 3:** You keep drawing balls, with replacement, until you have drawn 4 red balls. **No** 😞

# The binomial distribution

---

The PMF (probability distribution) for a binomially-distributed random variable:

$$P(X = k) = \binom{n}{k} p^k (1 - p)^{(n-k)} = \binom{n}{k} p^k q^{(n-k)}$$

The **binomial coefficient**:  $\binom{n}{k} = \frac{n!}{k!(n-k)!}$

- read as "n choose k"

# Wikipedia weighs in

## binomial

Probability mass function

Cumulative distribution function

# The binomial distribution

---

The **expectation** for a binomial r.v.

- $\mathbb{E}(X) = \mu = np$

The **variance** for a binomial r.v.

- $Var(X) = \sigma^2 = npq = np(1 - p)$

We write binomially distributed r.v.'s as  $X \sim B(n, p)$

# Example: Playing with a binomial rv

---

Each child born to a particular set of parents has a 25% probability of having blood type O. Assume the parents had five children.

Here,  $n = 5$  and  $p = 0.25$ , meaning we define Type O as "success", and not Type O as "failure".  $\rightarrow X \sim B(5, 0.25)$

## Tasks:

- Compute expectation and variance
- Visualize PMF
- Visualize CDF
- Make some calculations...

# Expectation and variance

---

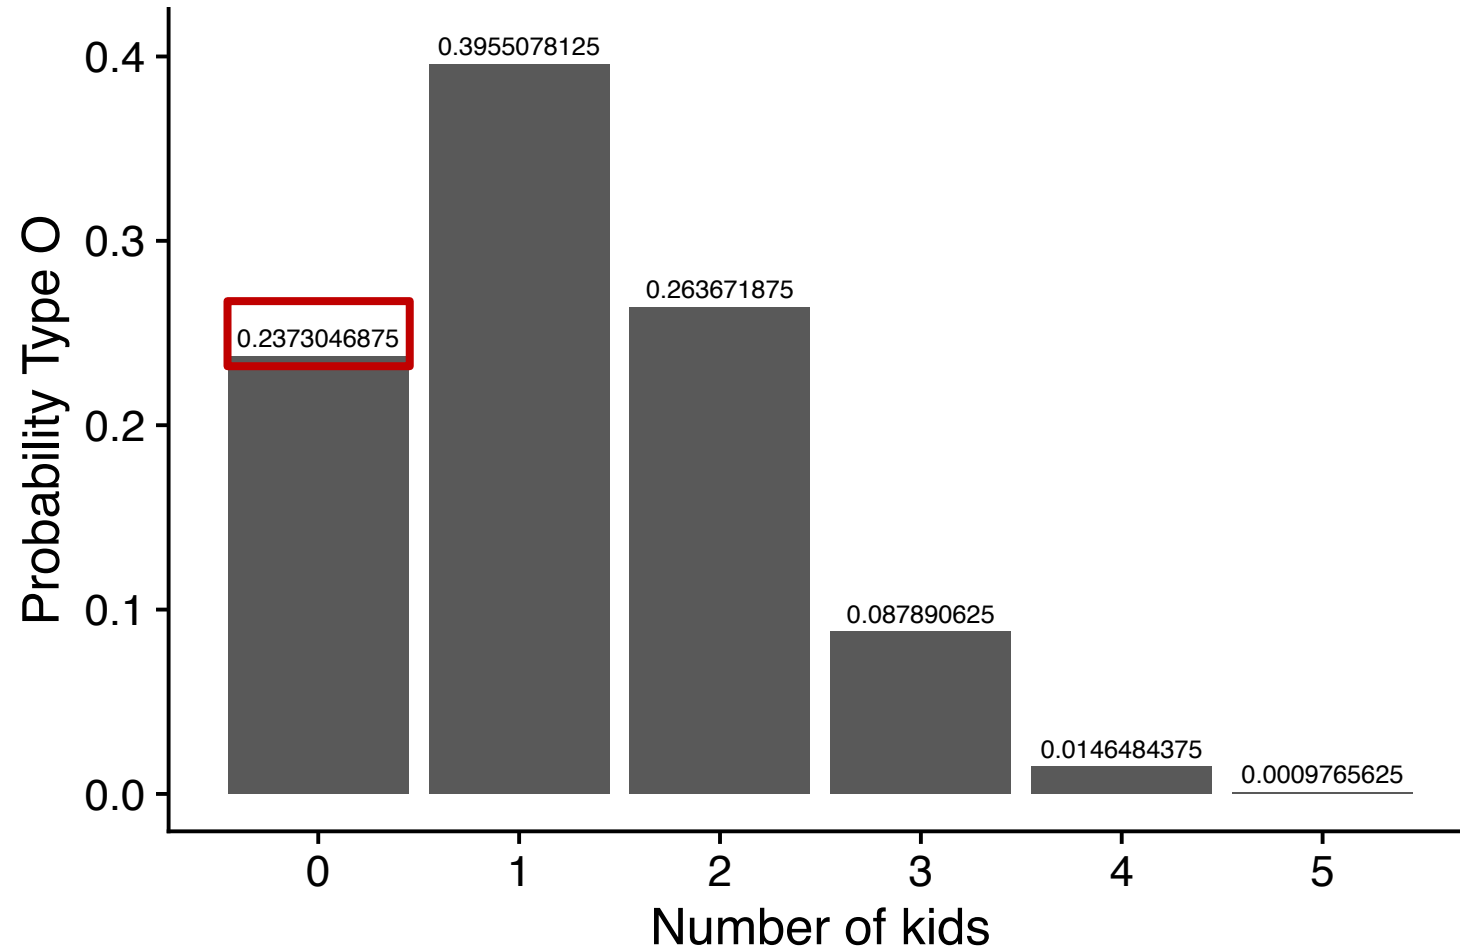

Each child born to a particular set of parents has a 25% probability of having blood type O. Assume the parents had five children.  $B(5, 0.25)$

$$\mathbb{E}(X) = \mu = np = 5 * 0.25 = 1.25$$

$$Var(X) = \sigma^2 = npq = np(1 - p) = 5 * 0.25 * 0.75 = 0.9375$$

# Visualize the PMF

---

# ?distributions

---

## Distributions in the stats package

### Description:

Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in the 'stats' package.

### Details:

The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form 'dxxx', 'pxxx', 'qxxx' and 'rxxx' respectively.

For the beta distribution see 'dbeta'.

For the binomial (including Bernoulli) distribution see 'dbinom'.

For the Cauchy distribution see 'dcauchy'.

For the chi-squared distribution see 'dchisq'.

# Distribution functions, generally

---

Function	Purpose	Binomial version
<code>dxxx()</code>	Probability distribution	<code>dbinom(x, size, prob)</code>
<code>pxxx()</code>	CDF	<code>pbinom(q, size, prob)</code>
<code>rxxx()</code>	Generate random numbers from given distribution	<code>rbinom(n, size, prob)</code>
<code>qxxx()</code>	Quantile: Inverse of <code>pxxx()</code>	<code>qbinom(p, size, prob)</code>

# Binomial distribution functions

Binomial function	Example	Output
<code>dbinom(x, size, prob)</code>	<code>dbinom(2, 5, 0.25)</code>	Prob of obtaining 2 successes in 5 trials, where $p=0.25 \rightarrow$ <b>0.263</b>
<code>pbinom(q, size, prob)</code>	<code>pbinom(2, 5, 0.25)</code>	Prob of obtaining $\leq 2$ successes in 5 trials, where $p=0.25 \rightarrow$ <b>0.896</b>
<code>rbinom(n, size, prob)</code>	<code>rbinom(100, 5, 0.25)</code>	Generate 100 k values from this binomial dist. $\rightarrow$ <b>100 from {0,1,2,3,4}</b>
<code>qbinom(p, size, prob)</code>	<code>qbinom(0.896, 5, 0.25)</code>	Smallest value $x$ where $F(x) \geq p^* \rightarrow$ <b>2</b> <small>*not prob success, just a prob</small>

# Making the PMF

```
> ## Use dbinom() to get the PMF values
> p = 0.25
> n = 5
> k0 <- dbinom(0, 5, 0.25) ## Prob of 0 successes, aka no children are Type 0
> k1 <- dbinom(1, 5, 0.25) ## Prob of 1 success, aka only 1 child is Type 0

> ## Advanced:
> library(purrr)
> map_dbl(0:5, dbinom, 5, 0.25)
[1] 0.2373046875 0.3955078125 0.2636718750 0.0878906250 0.0146484375
[6] 0.0009765625
```

# Making the PMF

---

```
## data frame (tibble) of probabilities for PMF
> data.pmf <- tibble(k = 0:5, prob = c(0.236623, 0.396, 0.264, 0.0879, 0.0145,
0.000977))
> data.pmf
# A tibble: 6 x 2
      k      prob
  <int>  <dbl>
1     0 0.236623
2     1 0.396000
3     2 0.264000
4     3 0.087900
5     4 0.014500
6     5 0.000977

## Equivalent
> data.pmf <- tibble(k = 0:5, prob = map_dbl(0:5, dbinom, 5, 0.25))
```

# Making the PMF uses a different `*stat*`

---

```
> ggplot(data.pmf, aes(x = k, y=prob))+ geom_bar( stat="identity" ) +  
  xlab("Number of kids") + ylab("Probability Type 0")
```

# Tweaking the x-axis

---

```
> ggplot(data.pmf, aes(x = k, y=prob))+ geom_bar( stat="identity" ) +  
  ylab("Probability Type 0") +  
  scale_x_continuous(name = "Number of kids", breaks = 0:5)
```

# Adding some text

---

```
> ggplot(data.pmf, aes(x = k, y=prob))+ geom_bar( stat="identity" ) +  
  ylab("Probability Type 0") +  
  scale_x_continuous(name = "Number of kids", breaks = 0:5) +  
  geom_text(aes(x = k, y= prob + 0.01, label = prob))
```

# Visualize the CDF

---

```
> binom.sample <- tibble(x = rbinom(1000, 5, 0.25))  
> ggplot(binom.sample, aes(x=x)) + stat_ecdf() +  
  xlab("# Type O kids") + ylab("Cumulative probability")
```

# Solving for probabilities

Each child born to a particular set of parents has a 25% probability of having blood type O. Assume the parents had five children.  $B(5, 0.25)$

What is the probability that exactly 2 children were Type O?

```
> dbinom(2, 5, 0.25)
[1] 0.2636719
```

# Solving for probabilities

Each child born to a particular set of parents has a 25% probability of having blood type O. Assume the parents had five children. **B(5, 0.25)**

What is the probability that exactly 2 children were Type O?

$$P(X = k) = \binom{n}{k} p^k (1 - p)^{(n-k)} = \binom{n}{k} p^k q^{(n-k)}$$

$$\begin{aligned} P(X = 2) &= \binom{5}{2} 0.25^2 0.75^{(5-2)} \\ &= 10 * 0.0625 * 0.422 = \mathbf{0.26375} \end{aligned}$$

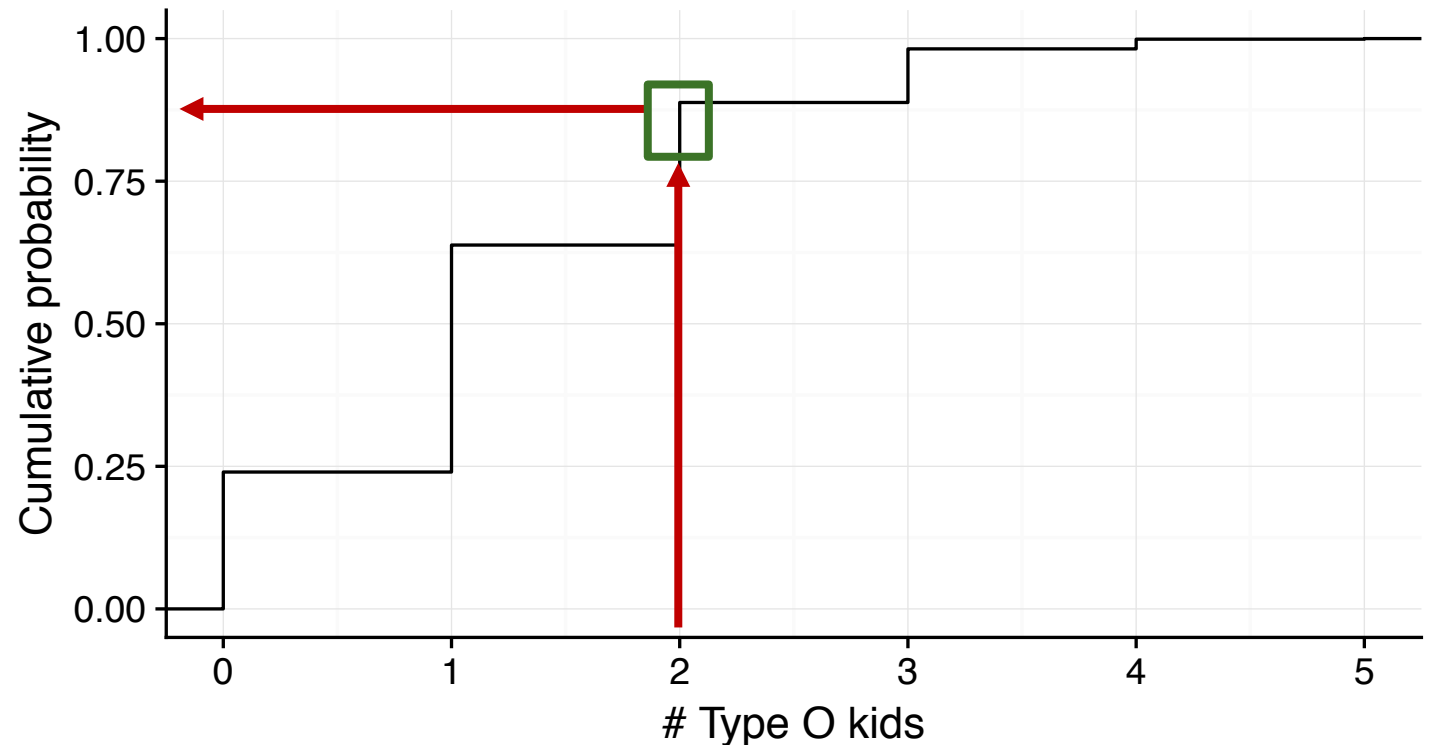

# Solving for probabilities

$B(5, 0.25)$

What is the probability that 2 or fewer children were Type O?

```
> pbinom(2, 5, 0.25)  
[1] 0.8964844
```

# Solving for probabilities

$B(5, 0.25)$

What is the probability that 2 or fewer children were Type O?

```
> dbinom(0, 5, 0.25) +  
  dbinom(1, 5, 0.25) +  
  dbinom(2, 5, 0.25)
```

```
[1] 0.8964844
```

# Solving for probabilities

$B(5, 0.25)$

What is the probability that *more than 2* children (ie either 3, 4, or 5) were Type O?

```
> 1 - pbinom(2, 5, 0.25)  
[1] 0.1035156
```

# Solving for probabilities

$B(5, 0.25)$

What is the probability that *more than 2* children (ie either 3, 4, or 5) were Type O?

```
> dbinom(3, 5, 0.25) +  
  dbinom(4, 5, 0.25) +  
  dbinom(5, 5, 0.25)
```

```
[1] 0.1035156
```

# BREATHE

---

# Expressing continuous random variables

---

## Probability density function (PDF)

- Describes the values taken by a continuous r.v.  $\mathcal{X}$  and its associated probabilities
- Function such that the area under the curve between any two points  $a, b$  corresponds to the probability that the r.v. falls between  $a, b$
- $\rightarrow P(a \leq X \leq b) = \int_a^b f(x)dx$

# PDF

---

# PDF properties

---

Continuous r.v.'s are *infinitely precise*:  $P(X = x) = P(x \leq X \leq x) = 0$

- Exactly unlike PMFs

Total area under the PDF equals 1:  $\int_{-\infty}^{\infty} f(x)dx = 1$

Probabilities aren't negative:  $f(x) \geq 0$

# Expressing continuous random variables

## Cumulative distribution function (CDF)

- Function defined, for a specific value  $x$  of a continuous r.v.  $\mathcal{X}$ , as  $\mathcal{F}(x) = \mathcal{P}(\mathcal{X} \leq x)$
- (mostly) the same as for discrete

# Relationship between PDF and CDF

---

# Jumping right in: Normal distribution

---

The PDF (probability distribution) for a normally-distributed random variable:

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left\{-\frac{(x-\mu)^2}{2\sigma^2}\right\}$$

It's gross, everyone knows it, and you will be neither plugging nor chugging with this equation

We write normally distributed r.v.'s as  $X \sim N(\mu, \sigma^2)$

# PDF of normal distribution

---

**Example**, let's say women's heights (cm) are normally distributed according to  $N(165, 64)$

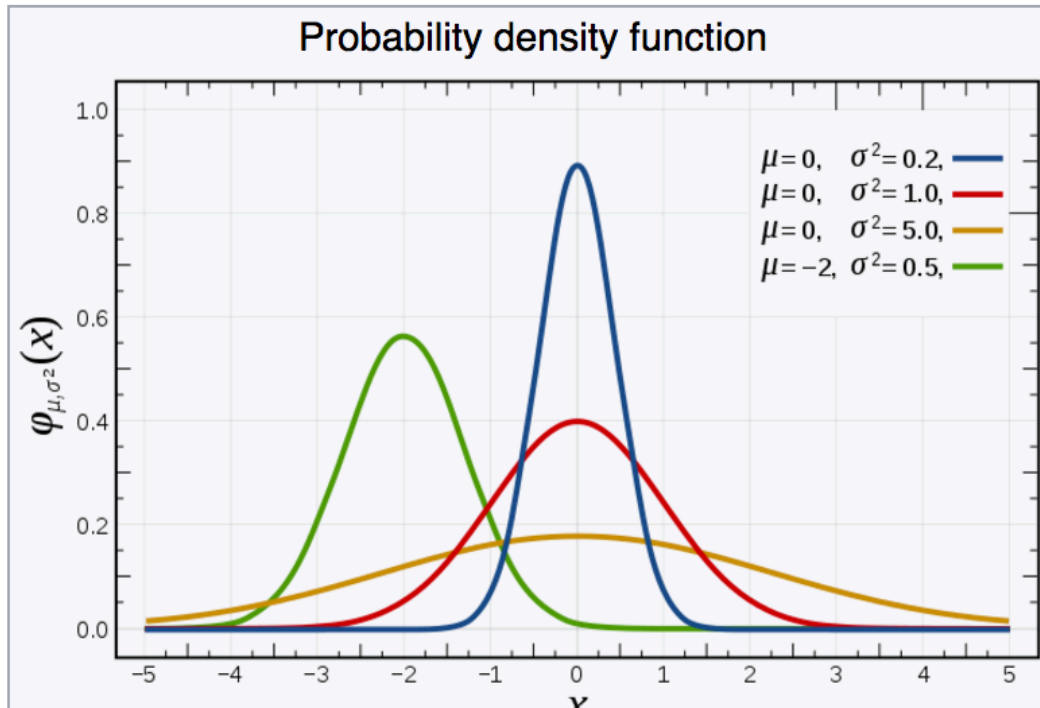

- Pop quiz: what is the standard deviation of this distribution?

# Wikipedia weighs in

## Normal distribution

Probability density function

Cumulative distribution function

# Making the PDF

---

Another "interesting" hack:

```
> plot.range <- tibble(x = c(165 - 32, 165 + 32))  
> ggplot(plot.range, aes(x=x)) +  
  stat_function(fun = dnorm, args=list(mean=164, sd=8))
```

# Making the CDF

---

```
> data.cdf <- tibble(x = rnorm(10000, 164, 8))  
> ggplot(data.cdf, aes(x=x)) + stat_ecdf()
```

# Expectation and variance

---

Any guesses?

It's in the definition:  $X \sim N(\mu, \sigma^2)$

# Working with the normal distribution

---

Types of questions one can ask:

- What is the probability that a randomly-chosen woman is taller than 158 cm?
- What is the probability that a randomly-chosen woman is between 163—170 cm tall?
- What is the probability that a randomly-chosen woman is shorter than 167 cm?
- What is the probability that a randomly-chosen woman is 168 cm tall?

# Working with the normal distribution

---

## Types of questions one can ask:

- What is the probability that a randomly-chosen woman is taller than 158 cm?
- What is the probability that a randomly-chosen woman is between 163—170 cm tall?
- What is the probability that a randomly-chosen woman is shorter than 167 cm?
- ~~◦ What is the probability that a randomly-chosen woman is 168 cm tall?~~

# Properties of the normal distribution

Symmetric around the mean

Mean = median = mode

**Inflection  
points**

# Introducing the **standard normal**: $X \sim N(0,1)$

# Standard Normal $X \sim N(0,1)$

---

# PDF and CDF of $X \sim N(0,1)$

# Standard Normal $X \sim N(0,1)$

---

Due to symmetry,  $P(X \leq -x) = 1 - P(X \leq x)$

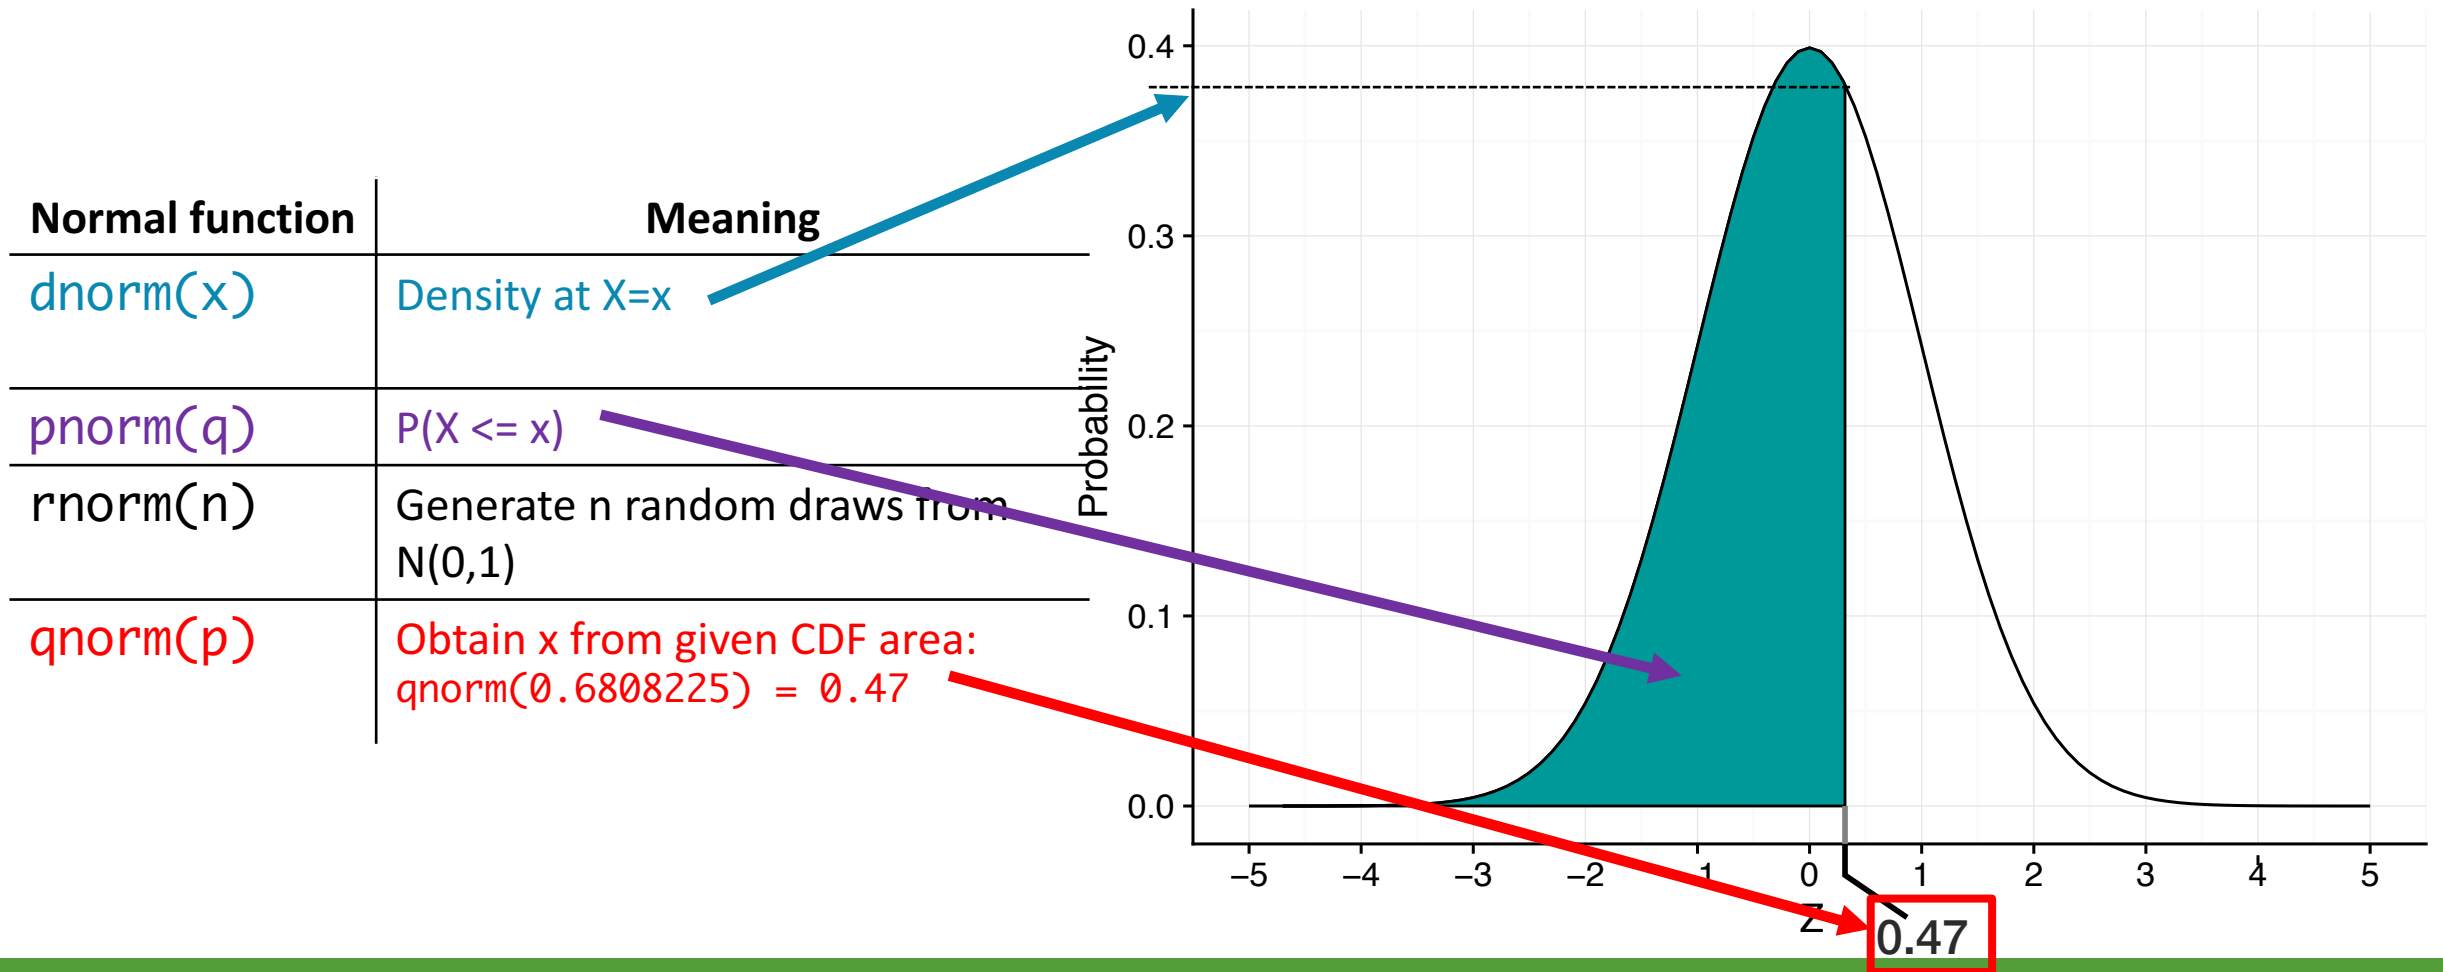

For  $X \sim N(0,1)$ , what is the probability  $P(X \leq 0.47)$ ?

---

```
# CDF: P(X <= 0.47)
> pnorm(0.47)
[1] 0.6808225
```

# Normal distribution functions

For  $X \sim N(0,1)$ , what is the probability  $P(-1.32 \leq x \leq 0.47)$ ?

---

For  $X \sim N(0,1)$ , what is the probability  $P(-1.32 \leq x \leq 0.47)$ ?

---

0.587405

=

```
# P(X <= 0.47)
> pnorm(0.47)
[1] 0.6808225
```

-

```
# P(X <= -1.32)
> pnorm(-1.32)
[1] 0.09341751
```

For  $X \sim N(0,1)$ , what is the probability  $P(-1 \leq x \leq 1)$ ?

---

AKA probability of being within 1 standard deviation of mean?

**~0.68**

# For $X \sim N(0,1)$ , what is the probability $P(x \geq 2.14)$ ?

---

## Two approaches:

```
> 1 - pnorm(2.14)  
[1] 0.01617738
```

```
> pnorm(-2.14)  
[1] 0.01617738
```

For  $X \sim N(0,1)$ , the top 8% of the distribution falls above what number?

---

```
> qnorm(1 - 0.08)
[1] 1.405072

> -1 * qnorm(0.08)
[1] 1.405072
```

# Historical consideration of z-scores

# Re-scaling to standard normal to compare distributions

---

$$Z = \frac{x - \mu}{\sigma}$$

- $x$  = distribution value of interest ("raw score")
- $\mu, \sigma$  = r.v./population mean, standard deviation

# Example: Weight for a population of rabbits follows a normal distribution $N(2.6, 1.1)$

---

What is the Z-score for a 3 pound rabbit?

$$Z = \frac{x - \mu}{\sigma} = \frac{3 - 2.6}{\sqrt{1.1}} = \mathbf{0.381}$$

Does it make sense that this number is positive?

What is probability a rabbit weighs less than 3 pounds?

$$\text{pnorm}(0.381) = 0.648$$

$$\text{pnorm}(3, 2.6, \text{sqrt}(1.1)) = 0.648$$

**THE FUTURE IS NOW**

# Normal distributions functions, revisited

---

All functions assume standard normal. Provide additional arguments for other normals:

Standard normal	Any normal
$\text{pnorm}(q) = \text{pnorm}(q, 0, 1)$	$\text{pnorm}(q, \text{mean}, \text{sd})$

# Z-scores are most useful for comparing different distributions

---

Weight for rabbit pop A is distributed  $N(2.6, 1.1)$

Weight for rabbit pop B is distributed  $N(2.9, 0.17)$

Which of these two rabbits is bigger? Pop A rabbit weighting 2.95 lbs, or pop B rabbit weighing 3.1 lbs?

$$\text{Population A: } Z = \frac{x - \mu}{\sigma} = \frac{2.95 - 2.6}{\sqrt{1.1}} = 0.334$$

$$\text{Population B: } Z = \frac{x - \mu}{\sigma} = \frac{3.1 - 2.9}{\sqrt{0.17}} = 0.485$$

# Putting it all together

---

The height of European men is distributed as  $N(175, 53.3)$

The height of European women is distributed as  $N(162.5, 34.8)$

What proportion of men is shorter than 150 cm, aka  $P(\text{man} < 150)$ ?

**Using Z-scores**

$$Z = \frac{x - \mu}{\sigma} = \frac{150 - 175}{\sqrt{53.3}} = -3.424$$

```
> pnorm(-3.424)
[1] 0.0003085331
```

**Skipping Z-scores**

```
> pnorm(150, 175, sqrt(53.3))
[1] 0.0003081516
```

# Putting it all together

---

Men:  $N(175, 53.3)$   
Women:  $N(162.5, 34.8)$

What proportion of women is taller than 162.5 cm? **50%**

# Putting it all together

---

Men:  $N(175, 53.3)$   
Women:  $N(162.5, 34.8)$

What proportion of women is taller than 170 cm?

## Using Z-scores

$$Z = \frac{x - \mu}{\sigma} = \frac{170 - 162.5}{\sqrt{34.8}} = 1.2713$$

```
> 1 - pnorm(1.2713)
[1] 0.101811
```

## Skipping Z-scores

```
> 1 - pnorm(170, 162.5,
sqrt(34.8))
[1] 0.1017987
```

# Putting it all together

---

Men:  $N(175, 53.3)$   
Women:  $N(162.5, 34.8)$

What is the tallest a woman can be and still be in the bottom 22%?

## Using Z-scores

```
> qnorm(0.22)
[1] -0.7721932
```

$$Z = \frac{x - \mu}{\sigma} \rightarrow x = Z\sigma + \mu$$

$$\begin{aligned} &= -0.7722 * \sqrt{34.8} + 162.5 \\ &= \mathbf{157.9 \text{ cm}} \end{aligned}$$

## Skipping Z-scores

```
> qnorm(0.22, 162.5, sqrt(34.8))
[1] 157.9447
```

# Putting it all together

---

Men:  $N(175, 53.3)$   
Women:  $N(162.5, 34.8)$

What is the **shortest** a woman can be and still be in the **top 22%**?

## Using Z-scores

```
> -1 * qnorm(0.22)
[1] 0.7721932
```

$$\begin{aligned} Z &= \frac{x - \mu}{\sigma} \rightarrow x = Z\sigma + \mu \\ &= 0.7722 * \sqrt{34.8} + 162.5 \\ &= \mathbf{167.05 \text{ cm}} \end{aligned}$$

## Skipping Z-scores

```
> qnorm(1-0.22, 162.5, sqrt(34.8))
[1] 167.0553
```

# Putting it all together

---

Men:  $N(175, 53.3)$   
Women:  $N(162.5, 34.8)$

What is the probability a randomly chosen man is between 175–182 cm tall?

$$\rightarrow P(X < 182) - P(X < 175) = P(X < 182) - 0.5$$

```
> pnorm(182, 175, sqrt(53.3)) - 0.5  
[1] 0.3311738
```

# Putting it all together

Men:  $N(175, 53.3)$   
Women:  $N(162.5, 34.8)$

What is the probability a randomly chosen man is either between 175–182 cm tall or between 150–160 cm tall?

$$\rightarrow P(175 < X < 182) + P(150 < X < 160)$$

```
### First probability
```

```
> pnorm(182, 175, sqrt(53.3)) - 0.5  
[1] 0.3311738
```

```
> ### Second prob.
```

```
> pnorm(160, 175, sqrt(53.3)) - pnorm(150, 175, sqrt(53.3))  
[1] 0.01965059
```

```
> 0.3311738 + 0.01965059  
[1] 0.3508244
```

# Putting it all together

---

Men:  $N(175, 53.3)$   
Women:  $N(162.5, 34.8)$

I have two randomly-chosen European friends, one man and one woman each. What is the probability the man is at least 180 cm and the woman is between 163—170 cm?

$$\rightarrow P(\text{man} > 180) \times P(163 < \text{woman} < 170)$$

```
### First probability
```

```
> 1 - pnorm(180, 175, sqrt(53.3))  
[1] 0.2467138
```

```
> ### Second prob.
```

```
> pnorm(170, 162.5, sqrt(34.8)) - pnorm(163, 162.5, sqrt(34.8))  
[1] 0.3644282

# BREAK

---

# Statistical inference

---

# Two main flavors of statistical inference

---

## Estimation

- Estimate a population parameter from sample data
- Point estimates: What is the population mean?
- Interval estimates: In what range of values is the population mean likely to fall?

## Hypothesis testing

- Test whether the value of a population parameter is equal to some specific value
- Is there evidence that my sample differs from some underlying population?

# The sampling distribution

---

The probability distribution of values for an estimate that we obtain under sampling

# Obtaining a sampling distribution

---

```
> genes <- read.csv("genes.csv")
> head(genes)
  nucleotides
1       3785
2       7416
3       2135
4       7682
5       5766
6      11079

> mean(genes$nucleotides)
[1] 2761.039
> sd(genes$nucleotides)
[1] 2037.645
```

```
> ggplot(genes, aes(x=nucleotides)) +
  geom_histogram(fill="white", color="black")
```

# Obtaining a sampling distribution

### the function `sample_n` draws a random sample of rows

```
> small.sample <- genes %>% sample_n(25)
> mean(small.sample$nucleotides)
[1] 2151.8
```

The sample mean for a random sample of N=25 is  $\bar{x} = 2151.8$

```
> ggplot(small.sample , aes(x = nucleotides)) +
  geom_histogram() +
  geom_vline(xintercept=2151.8, color="blue") +
  geom_vline(xintercept= 2761.039, color="red")
```

```
geom_vline(xintercept=...)
geom_hline(yintercept=...)
geom_abline(yintercept=..., slope=...)
```

# Obtaining a sampling distribution

---

Now imagine we draw **20** samples of  $N=25$  and compute each of their means:

```
> head(n20.means)
  sample.mean
1    2584.84
2    2574.12
3    2382.64
4    3143.68
5    2252.56
6    2368.44
```

**Sampling distribution of the mean**

# Quantifying the sampling distribution

---

**The standard error** is the standard deviation of the estimate of the sampling distribution

- Standard error of the mean:  $SE_{\bar{x}} = \frac{s}{\sqrt{n}}$
- SE is **not** the standard deviation of a sample
- Here, n represents the number of samples (**not** the sample size)

It also quantifies the **precision of our estimate**, i.e. how far from the population parameter we are

# Computing the standard error of the mean

---

```
> head(n20.means)
  sample.mean
1    2584.84
2    2574.12
3    2382.64
4    3143.68
5    2252.56
6    2368.44

> sd(n20.means$sample.mean) / sqrt(20)
[1] 93.11888
```

**Sampling distribution of the mean**

# Several sampling distributions comprised of $N$ samples, each of $n=25$

---

**$N=20$**

**$N=50$**

**$N=100$**

**$N=1000$**

**$N=10000$**

# Standard error decreases as N increases

**N=20**

**SE = 93.1**

**N=50**

**SE = 58.1**

**N=100**

**SE = 37.9**

**N=1000**

**SE = 13.3**

**N=10000**

**SE = 4.02**

Therefore, mean of sampling distribution approaches population mean **2761.039**

---

**N=20**

**SE = 93.1**

**$\bar{x} = 2780.89$**

**N=50**

**SE = 58.1**

**$\bar{x} = 2753.91$**

**N=100**

**SE = 37.9**

**$\bar{x} = 2781.51$**

**N=1000**

**SE = 13.3**

**$\bar{x} = 2777.02$**

**N=10000**

**SE = 4.02**

**$\bar{x} = 2763.82$**

# The Central Limit Theorem

---

As sample size increases, **the sampling distribution of the mean** will be approximately **normal** regardless of true population distribution

# Next week..

---

Introduction to hypothesis testing and comparing means

More fun facts on estimation will come later in the semester,  
to be bundled with \*likelihood\*
